If you're looking for a way to run NetBench, the industry standard of network benchmark, in a smaller environment (and you almost have to, since NetBench's infrastructure requirements are so significant), here's the solution. This site allows you to emulate the NetBench test; it uses the client.txt load description file of the real NetBench startup to get the same load on the set of replacement tests that you can download here. NetBench emulators consist of dbench, tbench, and smbtorture. Dbench measures the load of the file system using I/O calls, tests network calls with TCP and process load, and smbtorture measures the stress load of your network. (If your browser makes the headline http:// the address bar, click here. And links to all major search engines and databases. This free site will tell you everything you need to know about finding the right places to get listed.2. Send your URL to nearly 600 search engines in one step with a dynamic view You fill out one form; the program does the rest for you automatically. Cost: \$70. Free trial will present your list on 10 randomly selected sites.3. Read web promotion strategies. by downloading Search Engine Tactics, a free e-book from the Internet Marketing Library. It's packed with tips on how to push your website to the top of the results List. Coordinates: WebStep Top 100, www.mmgco.com/top100.html; Dynamic View 2000, www.datacomms.com; Internet Marketing Library, W3C W3C www.foreverweb.com Wide Web Consortium (W3C) is working to eliminate the text password using your phone as an authentic. Like the two-factor authentication we use today, the W3C password solution will work for any site because it's a browser-based, not an account. This W3C password solution is already working with Mozilla Firefox, with a large number of browsers on the way. The death of the password is a topic that has been in discussion for years, but just yesterday I signed up for an account on the site and created a text password. Obviously, as much as the tech world would like to eliminate passwords, they will still be strong. The World Web Consortium (W3C), an international Internet standards organization founded by Tim Berners-Lee, in conjunction with the FIDO Alliance, has a real solution in the pipeline. In a recent recommendation, more than a dozen W3C members outlined a plan to use mobile devices as an authentic for your web accounts. You're probably thinking: Aren't we already doing this? Yes, we certainly use our phones for two-factor authentication (for example, when you receive a text message with the code to enter the form), as well as for hardware authentication (when your phone notifies you that you have entered Gmail from a new location). The difference with this recent W3C password offering is that it will be browser-based and not account-based, so that any site on the internet can take advantage of the system. Here's how it works: You visit the site on your phone and create a new account. Phone tells you: Do you want to register this device on this site? You agree to register. The phone asks you to verify the authenticity of your identity using fingerprint/PIN/pattern code. Your account has been created. Later, you visit the same site on your laptop and press the Login button. You enter your username, but not your password. Instead, your phone is a beep. Do you see a hint along the lines, do you want to enter the example.com? You confirm and once again verify the authenticity of your identity using a fingerprint/PIN/pattern. A web page on your laptop instantly registers you. No password required. This makes it more difficult than having a password, but it's more secure by a significant margin. It also makes it incredibly difficult for identity theft to access your account on multiple sites by detecting a single password. You may ask: What if a thief steals my phone? Hopefully you have some remote swipes set up on your device, so once your phone gets stolen, you can disable it as an authentic. If you don't have this setup yet, you should take care of that as soon as possible. Of course, this whole system only works if browsers adopt the technology. Fortunately, Mozilla Firefox is already on board, with Google Chrome, Opera, and Microsoft Edge soon. Only Apple keeps out so far. You can read more about how the system works in detail here and you can read more about W3C and what its mission is here. Next: Next: the best Android security apps that aren't antivirus apps
